puzzle

Dynamic  
programming  
vs. Greedy

This course in

- Strategies for solving more difficult problems, or general algorithms for solving certain types of problems
- A problem may be solved using more than one method - you have to select the most efficient one
- In order to apply one of the methods described here, the problem needs to satisfy certain criteria

# Divide and conquer - steps

## Lecture 13

## Divide and conquer

### Backtracking

Introduction  
Generate and test

Backtracking  
Recursive and iterative

### Greedy

### Dynamic programming

Longest increasing subsequence

Maximum subarray sum  
0-1 Knapsack problem

Egg dropping puzzle

### Dynamic programming vs. Greedy

This course in

- **Divide** - divide the problem (instance) into smaller problems of the same structure
  - Divide the problem into two or more disjoint sub problems that can be resolved using the same algorithm
  - In many cases, there are more than one way of doing this
- **Conquer** - resolve the sub problems recursively
- **Combine** - combine the problems results

## Remember

Typical problems for Divide & Conquer

#### Dynamic programming vs. Greedy

This course in

When can divide & conquer be applied?

- A problem  $P$  on the data set  $D$  may be solved by solving the same problem  $P$  on other data sets,  $d_1, d_2, \dots, d_k$ , of a size smaller than the size of  $D$ .

The running time for solving problems in this manner may be described using recurrences.

$$T(n) = \begin{cases} \text{solve trivial problem, } n \text{ small enough} \\ k * T(\frac{n}{k}) + \text{divide time} + \text{combine time, otherwise} \end{cases}$$

# Step 1 - Divide

- Simplest way: divide the data into 2 parts (*chip and conquer*): data of size 1 and data of size  $n-1$
- Example: Find the maximum

```
def findMax(data):  
    '''  
    Find the greatest element in the list  
    input: data — list of elements  
    output: maximum value  
    '''  
  
    if len(data) == 1:  
        return data[0]  
    # Divide into subproblems of sizes 1 and (n-1)  
    maxVal = findMax(data[1:])  
    # Combine  
    if maxVal > data[0]:  
        return maxVal  
    return data[0]
```

# Step 1 - Divide

Recursive and iterative

#### Greedy

#### Dynamic programming

Longest increasing subsequence

Maximum subarray sum

0-1 Knapsack problem

Egg dropping puzzle

#### Dynamic programming vs. Greedy

This course in

■ The recurrence is:  $T(n) = \begin{cases} 1, & n = 1 \\ T(n-1) + 1, & \text{otherwise} \end{cases}$

$$T(n) = T(n-1) + 1,$$

$$T(n-1) = T(n-2) + 1,$$

$$T(n-2) = T(n-3) + 1, \text{ so}$$

$$T(n) = 1 + 1 + 1 + \dots + 1 = n, T(n) \in \theta(n)$$

# Step 1 - Divide

## Lecture 13

Egg dropping  
puzzle

Dynamic  
programming  
vs. Greedy

This course in

- Divide into  $k$  data of size  $n/k$

```
def findMax(data):  
    '''  
    Find the greatest element in the list  
    input: data – list of elements  
    output: maximum value  
    '''  
    if len(data) == 1:  
        return data[0]  
    # Divide into two subproblems of size  $n/2$   
    mid = len(data) // 2  
    maxLeft = findMax(data[:mid])  
    maxRight = findMax(data[mid:])  
    # Combine  
    return max(maxLeft, maxRight)
```

# Step 1 - Divide

### Divide and conquer

#### Backtracking

Introduction  
Generate and test

Backtracking  
Recursive and iterative

#### Greedy

#### Dynamic programming

Longest increasing subsequence

Maximum subarray sum

0-1 Knapsack problem

Egg dropping puzzle

#### Dynamic programming vs. Greedy

This course in

- The recurrence is:  $T(n) = \begin{cases} 1, n = 1 \\ 2 * T(\frac{n}{2}) + 1, \text{otherwise} \end{cases}$

$$T(2^k) = 2 * T(2^{k-1}) + 1$$

$$2 * T(2^{k-1}) = 2^2 * T(2^{k-2}) + 2$$

$$2^2 * T(2^{k-2}) = 2^3 * T(2^{k-3}) + 2^2$$

If we denote  $n = 2^k$ , then  $k = \log_2 n$  and  $T(n) =$

$$1 + 2^1 + 2^2 + 2^3 + \dots + 2^k = \frac{2^{k+1} - 1}{2 - 1} = 2^{k+1} - 1 = 2n \in \Theta(n)$$

# Divide and conquer - Example

Longest increasing subsequence

Maximum subarray sum  
0-1 Knapsack problem

Egg dropping puzzle

#### Dynamic programming vs. Greedy

This course in

- Binary-Search ( $T(n) \in \theta(\log_2 n)$ )
  - Divide - compute the middle of the list
  - Conquer - search on the left or for the right
  - Combine - nothing
- Quick-Sort ( $T(n) \in \theta(n * \log_2 n)$ )
  - Divide - partition the array into 2 subarrays
  - Conquer - sort the subarrays
  - Combine - nothing
- Merge-Sort ( $T(n) \in \theta(n * \log_2 n)$ )
  - Divide - divide the list into 2
  - Conquer - sort recursively the 2 list
  - Combine - merge the sorted lists

# Backtracking

puzzle

Dynamic  
programming  
vs. Greedy

This course in

## What have we learned?

- The total number of checked arrays is  $3^3$ , and in the general case  $n^n$
- First the algorithm assigns values to all components of the array possible, and only afterwards checks whether the array is a permutation
- Implementation above is not general. Only works for  $n=3$

# Generate and test

vs. Greedy

This course in

- In general: if  $n$  is the depth of the tree (the number of variables in a solution) and assuming that each variable has  $k$  possible values, the number of nodes in the tree is  $k^n$ . This means that searching the entire tree leads to an exponential time complexity -  $O(k^n)$

# Generate and test

## Lecture 13

Arthur Molnar

Divide and  
conquer

Backtracking

Introduction  
**Generate and  
test**  
Backtracking  
Recursive and  
iterative

Greedy

Dynamic  
programming

Longest  
increasing  
subsequence  
Maximum  
subarray sum  
0-1Knapsack  
problem  
Egg dropping  
puzzle

Dynamic  
programming  
vs. Greedy

This course in

## Possible improvements

- Do not construct a complete array in case it cannot lead to a correct solution.
- e.g - if the first component of the array is 1, then it is useless to assign other components the value 1
- Work with a potential array (a partial solution)
- When we expand the partial solution verify some conditions (conditions to continue) - so the array does not contains duplicates

# Backtracking

This course in

## Test candidates - print only solutions

```
def generateAndTest(x, DIM):  
    if len(x) == DIM and isSet(x):  
        print(x)  
    if len(x) > DIM:  
        return  
    x.append(0)  
    for i in range(0, DIM):  
        x[-1] = i  
        generateAndTest(x[:], DIM)  
print(generate([], 3))
```

- We still generate all possible lists (e.g. starting with 0,0,...)
- We should not explore lists that contains duplicates (they cannot result in valid permutations)

Dynamic  
programming  
vs. Greedy

This course in

- A strategy to solve optimization problems.
- Applicable where the global optima may be found by successive selections of local optima.
- Allows solving problems without returning to previous decisions.
- Useful in solving many practical problems that require the selection of a set of elements that satisfies certain conditions (properties) and realizes an optimum.
- Disadvantages: Short-sighted and non-recoverable.

# Greedy - Sample Problems

This course in

## The knapsack problem

- A set of objects is given, characterized by usefulness and weight, and a knapsack able to support a total weight of  $W$ . We are required to place in the knapsack some of the objects, such that the total weight of the objects is not larger than the given value  $W$ , and the objects should be as useful as possible (the sum of the utility values is maximal).

## The coins problem

- Let us consider that we have a sum  $M$  of money and coins (ex: 1, 5, 25) units (an unlimited number of coins). The problem is to establish a modality to pay the sum  $M$  using a minimum number of coins

# Greedy - General case

This course in

- If a subset  $X$  fulfills the internal conditions we will say that the subset  $X$  is acceptable (possible).
- Some problems may have more acceptable solutions, and in such a case we are required to provide as good a solution as we may get, possibly even the better one, i.e. the solution that realizes the maximum (minimum) of a certain objective function.

Dynamic  
programming  
vs. Greedy

This course in

- The Greedy algorithm finds the solution in an incremental way, by building acceptable solutions, extended continuously. At each step, the solution is extended with the best candidate from  $C - B$  at that given moment. For this reason, this method is named greedy.
- The Greedy principle (strategy) is
  - Successively incorporate elements that realize the local optimum
  - No second thoughts are allowed on already made decisions with respect to the past choices.

# Greedy - General case

vs. Greedy

This course in

Assuming that  $\theta$  (the empty set) is an acceptable solution, we will construct set  $B$  by initializing  $B$  with the empty set and successively adding elements from  $C$ .

- The choice of an element from  $C$ , with the purpose of enriching the acceptable solution  $B$ , is realized with the purpose of achieving an optimum for that particular moment, and this, by itself, does not generally guarantee the global optimum.

This course in

More generally, the required elements are:

- 1 A **candidate set**, from which a solution is created.
- 2 A **selection function**, which chooses the best candidate to be added to the solution.
- 3 A **feasibility function**, that is used to determine if a candidate can be used to contribute to a solution.
- 4 An **objective function**, which assigns a value to a solution, or a partial solution.
- 5 A **solution function**, which will indicate when we have discovered a complete solution.

vs. Greedy

This course in

- Before applying Greedy, it is required to prove that it provides the optimal solution. Often, the proof of applicability is non-trivial.
- Greedy leads to polynomial run time. Usually, if the cardinality of the set  $C$  of candidates is  $n$ , Greedy algorithms have  $O(n^2)$  time complexity.

# Greedy - Remarks

Dynamic  
programming  
vs. Greedy

This course in

- There are a lot of problems that can be solved using Greedy, such as determining the shortest path between two nodes in an undirected or directed graph (Dijkstra's and Bellman-Kalaba's algorithms).
- There are problems for which Greedy algorithms do not provide optimal solution. In some cases, it is preferable to obtain a close to optimal solution in polynomial time, instead of the optimal solution in exponential time - these are known as *heuristic algorithms*.

# Greedy example - Interval scheduling

This course in

- The principle of optimality (in one of its form: forward, backward or mixed) is proven.
- The structure of the optimal solution is defined.
- Based on the principle of optimality, the value of the optimal solution is recursively defined. This means that recurrent relations, indicating the way to obtain the general optimum from partial optima, are defined.
- The value of the optimal solution is computed in a bottom-up manner, starting from the smallest cases for which the value of the solution is known.

## Problem statement

Let us consider the list  $a_1, a_2, \dots, a_n$ . Determine the longest increasing subsequence  $a_{i_1}, a_{i_2}, \dots, a_{i_s}$  of list  $a$ .

**e.g.** given sequence  $[0, 8, 4, 12, 2, 10, 6, 14, 1, 9, 5, 13, 3, 11, 7, 15]$ , a longest increasing subsequence is  $[0, 2, 6, 9, 11, 15]$ .

## Problem statement

Calculate the maximum sum of a subarray consisting of consecutive elements. e.g. for subarray **[-2, -5, 6, -2, -3, 1, 5, -6]** the maximum sum is 7 (6-2-3+1+5, as the numbers must be consecutive)

Dynamic  
programming  
vs. Greedy

This course in

## Naive implementation(s)

- 1 Uses 3 loops; one for interval start, one for interval end, one to calculate partial sum. At every step, compare obtained sum with previous maximum.
- 2 Uses 2 loops; final loop of previous implementation can be eliminated by calculating partial sums using the second loop

# Maximum subarray sum

This course in

## Divide & Conquer implementation

- 1 Divide** - The subarray we are searching for can be in one of only 3 places:
  - 1** Contained in left side of array.
  - 2** Contained in right side of array.
  - 3** Subarray includes middle element of array.
- 2 Conquer** - Calculate alternatives using 2 recursions and one  $O(n)$  algorithm. Final complexity is  $O(n * \log_2(n))$
- 3 Combine** - Return maximum value.

This course in

## Dynamic programming implementation

- We iterate over the array once (so  $O(n)$  complexity).
- For each index, we calculate the maximum array ending at that position. If the sum is a new maximum, we record it.

## Implementation

The source code for all implementations can be found in

## Problem statement

You have a collection of items, each having its own weight and utility. You have a knapsack with capacity  $W$ . Which of the items can you pack in order to maximize their utility. You cannot break up items (0-1 property), and you cannot pack the same item more than once (bounded version)

## Rules:

- All eggs are equivalent.
- An egg that survives a drop is unharmed and reusable.
- A broken egg cannot be reused.
- If an egg breaks when dropped from a given floor, it will also break when dropped from a higher floor.
- If an egg does not break when released from a given floor, it can be safely dropped from a lower floor.
- You cannot assume that dropping eggs from the first floor is safe, nor that dropping from the last floor is not.

This course in

What do we do in the  $n=1$  case?

- Drop the egg at each floor until it breaks or you've reached the top, starting from first (ground) floor.
- In this case, the maximum number of drops is equal to  $k$ , the number of floors the building has.

## Possible strategies for the $n=2$ case...

- 1 The  $n=1$  case was basically linear search, so we can try binary search with the first egg (drop it from the mid-level floor).
- 2 How about dropping from every 20th floor, starting from ground level?

**Let's try to describe the situation in a structured way...**

- Imagine we drop the first egg at a given floor  $m$ .
- If it breaks, we have a maximum of  $(m-1)$  drops, starting from ground.
- If it does not break, we increase by  $(m-1)$  floors, as we have one less drop.
- Following the same logic, at each step we decrease the number of floors by 1.

So, if we have **n=2** eggs and **k=100** floors?

- We solve

$$m + (m - 1) + (m - 2) + (m - 3) + (m - 4) + \dots + 1 \geq 100$$

- Solution is between 13 and 14, which we round to **14**.  
First drop is from floor 14

Now for the general case - building has  $k$  floors, and we have  $n$  eggs.

- **Optimal substructure** - Dropping an egg from floor  $x$  might result in two cases (subproblems):

- 1 **Egg breaks** - Problem is reduced to one with  $x-1$  floors and one fewer egg.
- 2 **Egg is ok** - Problem is reduced to one with  $k-x$  floors and same number of eggs.

This course in

- Both techniques are applied in optimization problems
- Greedy is applicable to problems for which the general optimum is obtained from partial (local) optima
- Dynamic programming is applicable to problems in which the general optimum implies partial optima.
